Authors’ contributions

This work was carried out in collaboration between all authors. Author JAM designed the study, performed the statistical analysis, wrote the protocol, and wrote the first draft of the manuscript. Authors AMS and IA managed the analyses of the study. Authors AAM, RII and IMI managed the literature searches. All authors read and approved the final manuscript.

ABSTRACT

The purpose of this study was to investigate the in-vivo and in-vitro potentials of ethyl acetate extract of P. americana leaf in alloxan-induced diabetic rats. Quantitative phytochemicals analyzed includes; flavonoids, saponins, tannins, alkaloids and phenolics. Measurement of antioxidant activity using 1,1-Diphenyl-2-picrylhydrazyl, total antioxidant capacity, hydroxyl radical, hydrogen peroxide, superoxide radical and ferric reducing activity of the extract was carried out. Hyperglycemia was induced by intraperitoneal injection of alloxan monohydrate to albino rats. In-vivo anti-oxidant potentials of the extract were evaluated by measuring liver homogenate activity of superoxide

INTRODUCTION

Diabetes mellitus ranked among the leading causes of death in developed countries and is one of the most prevalent metabolic disorders in the world [1]. Although several etiologies have been implicated, defects in insulin secretion, insulin action, or both are often the primary characteristic of the disease [2]. Long-term complications of diabetes include coronary heart diseases, retinopathy, nephropathy, and foot ulceration [3]. Alloxan (2,4,5,6-tetraoxypyrimidine; 5,6-dioxyuracil), one of the commonly used drugs for the induction of experimental diabetes in rats, is a diabetogenic agent that selectively destroys pancreatic β-cells [4]. Oxidative stress is defined as a state of overload due to imbalanced formation and elimination of highly reactive molecules including reactive oxygen species (ROS) as well as reactive nitrogen species (RNS) [5,6]. OS play a major role in reduced secretion by pancreatic β-cells, systemic inflammation, endothelial damage and impaired glucose consumption in peripheral tissues [7]. OS is associated with numerous deleterious consequences in which radicals speed up cellular destruction in many diseases and can attack proteins, lipids, DNA and cell death [8]. Medicinal plant is an important part of traditional health care system and a veritable health care source for the vast majority of the world population. It was estimated that 70-80% of people worldwide use herb for management of mild to moderate illnesses [9-13]. The Avocado (Persea americana Mill.), unflatteringly known in the past as alligator pear, midshipman’s butter and vegetable butter. It has traditionally been used due to its antibacterial, antifungal, hypotensive, anti-inflammatory, and immune-enhancing effects [14,15]. Furthermore, Avocado juice made from ripe fruit was very popular due to its numerous health benefits. Phenolic substances including lignoids, proanthocyanidins, and flavonoids with highly potent antioxidant properties have been reported as the predominating phytochemicals in avocado [16-20]. This present study seeks to validate the traditional use of Persea americana leaf extract in the management of DM and several oxidative stress induced diseases.

MATERIALS AND METHODS

2.1 Sample Collection, Identification and Preparation

The leaf of Persea americana was collected from Jos, Plateau state, Nigeria. It was authenticated by a Botanist at Plant Science Department, Bayero University, Kano with accession number BUKHAN 0326. The sample was chopped into small pieces and then shades dried and ground into powdered form. One hundred grams of the dried sample was exhaustedly extracted by soxhlet extraction using ethyl acetate as solvent.

2.2 Quantitative Analysis, In-vitro and In vivo Analysis

2.2.1 Determination of total phenolic content (TPC)

The quantification of TPC with different solvents of EPAL was carried out using the prescribed procedure reported by Wolfe K et al., using Folin

Keywords: Antioxidants; phytochemicals; Persea americana; oxidative stress; diabetes mellitus.
and the absorbance was read at 544 nm. The absorbance was calculated at 500 nm. Results were expressed as dioxegen equivalents (mg DE/g extract) derived from a standard curve.

2.2.6 In vitro antioxidant assays

Five different concentrations were used (1.2, 1, 0.8, 0.6, 0.4 and 0.2 µg/ml) for the assay. All experiments were conducted in triplicates and all the negative control (blank) was prepared using the same procedure replacing the ethyl acetate extract of P. americana leaf (EPAL) with distilled water. The free radical scavenging activity of the EPAL were evaluated with various solvents based on its scavenging activities on the stable 1, 1-diphenyl-2-picrylhydrazyl (DPPH) free radical according to the method described by Braca et al. [26]. Determination hydroxy radical scavenging potential of EPAL with various solvents to prevent Fe²⁺/H₂O₂ induced decomposition of deoxyribose was carried out using the modified method [27]. Determinations of superoxide anion radical scavenging potential of EPAL with various solvents were achieved according to the method [28]. The chelating of Fe²⁺ by EPAL with various solvents was estimated as described by Dinis et al. [29]. Ferric ions reducing power of the with various solvents’ extracts and standards were determined according to the method adopted by Müller et al. [30]. Total antioxidant capacity (TAC), was measured by a spectrophotometric method using a phoshomolybdenum method, which was based on the reduction of Mo⁷⁺ to Mo⁶⁺ by the sample analytes and the subsequent formation of green phosphate/Mo⁵⁺ compound with a maximum absorption at 695 nm. Sharp absorbance values proved the possession of significant antioxidant activity [31]. TAC was identified using the standard curve of vitamin C (equation: y = 2.046x + 0.043, r²= 0.991). To these above said antioxidant assays, the percentage inhibitory / scavenging activity of the EPAL / standard was calculated using following equation:

\[
EPAL = \frac{A0}{A0} \times \frac{A1}{A0} \times 100
\]

Where A0 is the absorbance of the control, and A1 is the absorbance of the EPAL / standard. The half maximal inhibitory concentration (IC₅₀) value were calculated from the linear regression equation using following equation- \( y = mx+c \), Where y is the percentage activity and equals 50, m is the slope, c is the intercept and x is the IC₅₀ value.
2.2.7 In vivo antioxidant activity (oxidative stress markers)

2.2.7.1 Preparation of liver homogenate

Liver homogenate was prepared according to the method described [32]. Dissected livers were excised, washed with ice-cold 0.9% NaCl (w/v) to remove the blood, cut into small pieces by fine scissors, and then homogenized (10% w/v) separately in ice-cold 1.15% KCl-0.01M sodium phosphate buffer, pH 7.4 with a homogenizer. The homogenate was centrifuged at 10,000 rpm for 20 min at 4°C. Supernatant of the liver homogenate was collected into sterilized tubes and stored at -20°C until analysis.

2.2.7.2 Superoxide dismutase

Liver homogenate of (0.1 ml) was diluted in 0.9 ml of distilled water to make 1:10 dilution. An aliquot (0.20 ml) of the diluted homogenate was added to 2.5 ml of 0.05 M carbonate buffer. The reaction was started with the addition of 0.3 ml of 0.3 mm Adrenaline. The reference mixture contained 2.5 ml of 0.05 M carbonate buffer, 0.3 ml of 0.3 mm Adrenaline and 0.20 ml of distilled water. Absorbance was measured at 30sec intervals up to 150 sec at 480nm in a spectrophotometer [33].

Calculation: Increase in absorbance per minute = \( (A5 - A1) \times 2.5 \)

% Inhibition = \( \frac{\text{Increase in absorbance for substrate}}{\text{Increase in absorbance of blank}} \times 100 \)

1 unit of SOD activity is the quantity of SOD necessary to elicit 50% inhibition of the oxidation of adrenaline to adrenochrome in 1 minute.

\[ \text{SOD Activity} = \frac{\% \text{ inhibition}}{50} \times \text{weight of tissue} \]

2.2.7.3 Catalase

Into two test tubes T0 and T1, 2ml of homogenate supernatant, 2 ml of phosphate buffer and 0.4ml of H2O2 was added and mixed. Immediately after, 1 ml of potassium dichromate/glacial acetic acid was added to T0. After 10 minutes, 1 ml of potassium dichromate/glacial acetic acid was also added to T1. The contents were mixed and incubated at 80°C for 10 minutes. The absorbance was measured at 570 nm against blank in a spectrophotometer [33].

\[ \text{CT} = \text{Concentration of Test, CS} = \text{Concentration of Standard} = 0.2M, \text{AT} = \text{Absorbance of Test (T0 - T1), AB = Absorbance of Blank (T0)} \]

\[ \text{Catalase Activity} = \frac{\text{CT} \times \text{total vol. Of homogenate}}{10 \text{ minutes}} \times \text{weight of tissue} \times \text{vol. Of homogenate used} \]

2.2.7.4 Glutathione reductase

To 150 μl of tissue homogenate, 1.5 ml of 10% TCA was added and centrifuged at 1500 g for 5 min. To a fresh test tube, 1 ml of the supernatant was added then 0.5 ml of Ellman’s reagent was added and mixed then and 3 ml of phosphate buffer was added. The contents were mixed and the absorbance was read at 412 nm against the blank in a spectrophotometer [35].

Calculation: CT = concentration of the test, CS = Standard concentration, AT = Absorbance of test, AS = Absorbance of standard

\[ \text{Gluthathione} = \frac{\text{CT} \times \text{total volume of homogenate}}{\text{Volume of homogenate used}} \times \text{weight of tissue} \]

2.2.7.5 Glutathione peroxidase

To non-enzymatic wells - add 120 μl of assay buffer and 50 μl of co-substrate mixture to three wells. To positive control wells (bovine erythrocyte GPx) - add 100 μl of assay buffer, 50 μl of co-substrate mixture, and 20 μl of diluted GPx (control) to three wells. To sample wells - add 100 μl of assay buffer, 50 μl of co-substrate mixture, and 20 μl of sample to three wells. To obtain reproducible results, the amount of GPx added to the well should cause an absorbance decrease between 0.02 and 0.135/min. Initiate the reactions by adding 20 μl of cumene hydroperoxide to all the wells being used. Make sure to note the precise time the reaction is initiated and add the cumene hydroperoxide as quickly as possible. Carefully shake the plate for a few seconds to mix. Read the absorbance once every minute at 340 nm using a plate reader to obtain at least 5 time points [36].

2.2.7.6 Malondialdehyde (MDA)

Aliquots of homogenate (1 ml) were incubated at 37°C for 3 hr in a metabolic shaker. Then 1 ml of 10% aqueous trichloroacetic acid (TCA) was added and mixed. The mixture was then
centrifuged at 800 g for 10 min. 1 ml of the supernatant was removed and mixed with 1 ml of 0.67% thiobarbituric acid in water and placed in a boiling water bath for 10 min. The mixture was cooled and diluted with 1 ml distilled water. The absorbance of the solution was then read at 535 nm in a spectrophotometer. The content of malondialdehyde (nmol/g wet tissue) was then calculated, by reference to a standard curve of malondialdehyde solution[37,38].

2.3 Experimental Animals

Albino wistar rats (70-100 g body weight) were purchased from Physiology department, Bayero University, Kano (B.U.K). They were kept in animal cages at the animal room of same Physiology department at a temperature of 25 degrees and humidity of 57%. They were acclimatized for 3 days and had free access to feed and water ad libitum prior to the studies. Ethical conditions governing the conducts of experiments with life animals as stipulated were strictly observed. Also, the experimental protocol was approved by the College of Health Science ethical committee.

2.3.1 Experimental design

A total of 30 Albino rats were used for this experiment and they were divided into six groups of 5 rats each.

- Group 1- normal rats
- Group 2- diabetic control rats
- Group 3- diabetic rats treated with EPAL (100 mg/kg).
- Group 4- diabetic rats treated with EPAL (200 mg/kg).
- Group 5- diabetic rats treated with EPAL 400 mg/kg).
- Group 6- diabetic rats treated with glucophage (84 mg/kg) [39].

The studies lasted for a period of four weeks. Liver tissue was harvested for oxidative stress markers determination [superoxide dismutase (SOD), catalase (CAT), glutathione reductase (GSH), glutathione peroxidase (GPx) and malondialdehyde (MDA)].

2.4 Statistical Analysis

Statistical package for social sciences (SPSS) version 17 software was used for all calculations and statistical analysis. Analyses were performed using student t-test at 95% confidence level with P = .05 being significant. Results were presented as mean ± standard deviation.

3. RESULTS

3.1 Quantitative Phytochemical Analysis

The result of quantitative analysis of ethyl acetate extract of P. americana leaf revealed the presence of significant (P=.05) high concentration of phenolics (184.1±0.6) which was then followed by flavonoids (115.8±2.1), with saponins (15.2±2.3) having the least concentration (Table 1).

3.2 In vitro Antioxidant Activity

Antioxidant capacity of EPAL was examined using six different assays. EPAL displayed significant (P=.05) radical scavenging potential against DPPH, Superoxide anion, total antioxidant capacity, hydroxyl radical and hydrogen peroxide. The activity was found to increase with increase in concentration of EPAL (Table 2). Fig.1 shows the dose response curves for the reducing power (FRAP) of EPAL. The result of this assay shows that the extract possesses high radical scavenging activity when compared with vitamin C.

| Table 1. Quantitative phytochemical analysis of ethyl acetate leaf extract of P. Americana |
|----------------|----------------|
| **Phytochemicals** | **Leaf** |
| Alkaloids (%) | 41.5 ± 1.8² |
| Flavonoids (mg RE/g) | 115.8 ± 2.1² |
| Tannis (%) | 21.2 ± 0.8² |
| Saponins (g) | 15.2 ± 2.3² |
| Phenolics (mg GAE/g) | 184.1 ± 0.6² |

Results are presented as Mean ± SD (n=5). Values bearing different superscripts are significantly different (P=.05).

3.3 In-vivo Antioxidant Activity

Superoxide dismutase, catalase, glutathione reductase and glutathione peroxidase activities were assayed in alloxan-induced diabetic rats administered with different doses of ethyl acetate extract of *P. americana* leaf. The levels of these oxidative stress markers were found to significantly increase (P=.05) when compared with diabetic control group. However, the level of malondyaldehyde was found to increase significantly in diabetic control group (P=.05) when compared with the treated groups (Table 3).

4. DISCUSSION

The activities of plant extracts in effecting any therapeutic or biological changes in diseased animals or living tissues are direct functions of the chemical constituents inherently present in them after extraction [40]. The use of plants in treating diseases is as old as civilization [41] and herbal medicine is still a major part of habitual treatment of different diseases [42]. Diverse uses of plants in treatment of wide variety of diseases can be attributed to the presence of the phytochemicals or biologically active compounds which could serve as a potential a source of drugs in herbal medicine. The quantitative phytochemical assays in this present study indicated the concentration of the different secondary metabolite. Phenolics and flavonoids are known to possess varying antioxidant activities [43,44]. Antioxidant activity of a medicinal plant cannot be concluded based on a single antioxidant test model[45]. Similar findings have been documented for the antioxidant and anti-inflammatory properties of Avocado [46]. It is noteworthy that the tested extract demonstrated the ability to neutralize the ROS at different degree which may due to the presence of polyphenols which has capability to directly scavenge superoxide and other ROS like hydroxyl and peroxyl radicals [47-48]. flavonoids are water soluble anti-oxidants and free radical scavengers which prevent oxidative cell damage by donating a hydrogen atom, breaking the free radical chain, or electron to stabilize the radical species [49]. Phytochemicals are currently receiving attention as a potential protector against variety of human disease, major flavonoids has been shown to have neutralizing effect on free radical and ROS like hydroxyl radical, superoxide radical, hydrogen peroxides [50]. Saponins, triterpenes and phytosterol have been demonstrated to scavenge superoxide anion [51].

The DPPH test reveals that the leaf has free radical scavenging ability. It is a free radical compound widely used to test the free radical scavenging ability of flavonoids. This research is in line with the work [16,52], who suggested that avocado leaves have strong antioxidant activity, which may help in preventing or slowing down the progression of various diseases associated with oxidative stress. Hydrogen peroxide is a non-radical molecule generated *in-vivo* by several enzymes or by dismutation of two molecules of superoxide anions, a reaction catalysed by superoxide dismutase. Phenolics identified from EPAL in this study are antioxidant in nature, their scavenging activity may be as a result of their ability to donates electrons to H$_2$O$_2$ neutralizing it to water. Hydrogen peroxide reacts with Fe$^{2+}$ ion by Fenton reaction to form a highly reactive hydroxyl radical (OH$^-$) which in turn reacts with organic molecules [53]. Ursolic acid, a phenolic compound was found to exhibit hydroxyl radical scavenging activity, perhaps through its hydrogen donating ability as well as scavenged superoxide anion [54,55]. Ethyl acetate extract of *P. americana* leaf was found to be rich in phyto-reductants such as flavonoids and phenolics, which could be the main contributor to their antioxidative properties as many studies affirmed that flavonoids and phenols offered the highest ability of scavenging activity in medicinal plants.

Oxidative stress is currently suggested as the mechanism underlying diabetes and its complications [56,57]. From the present study, it has been observed that in alloxan-induced hyperglycemic rats, there were significant decrease in SOD, CAT, GPx and GSH activities and enhanced lipid peroxidation (MDA) in the liver. The decreased SOD activity may be due to high level of free radicals with decreased antioxidant defense mechanisms [58,59]. The significantly increased SOD level in diabetic rats following the administration of *P. americana* extract suggests a positive modulatory role for the extract in the amelioration of the induced oxidative stress. The observed significant elevation of GSH content of the liver of ethyl acetate extract of *P. americana* (EPAL) treated rats indicate that, the extract might have either increased the biosynthesis of GSH or lowered the utilization of GSH due to decreased oxidative stress, or both. Induction of the hepatic GSH antioxidant system by chemopreventive agents was reported in several studies [60]. Glutathione peroxidase (GPx) is a relatively stable enzyme, but it may be inactivated under conditions of severe oxidative stress [61]. Decreased activity
of GPx in diabetic control could be directly explained by the low content of GSH found in these rats since GSH is a substrate for GPx. Glutathione, the most important antioxidant metabolite, plays an important role in maintaining good levels of GPx activity. This would cause an increased accumulation of superoxide radicals, which could further stimulate lipid peroxidation. Decline in the activity of SOD in diabetic tissue and blood has been reported in many studies [62]. A study [63] suggested that hyperglycaemia increased hydrogen peroxide production and down-regulated CAT gene expression. A study carried out by Giugliano et al. [64] oral administration of \textit{P. americana} fruit extract to hyperglycaemic rats tends to bring liver peroxides to near control levels, which could be as a result of improved antioxidant status. Catalase protects pancreatic cells from damage by hydrogen peroxide [65,66]. The increased MDA level in diabetic control rats may be due to the generation of free radical species potentiated by exposure to alloxan. Further, EPAL exerts a protective effect by scavenging MDA and elevating the activities of antioxidant enzymes in treated rats. The decreased activity of SOD in liver of diabetic control rats may be due to the enhanced lipid peroxidation or inactivation of the antioxidative enzymes. Medicinal plants with high flavonoid content have been reported to decrease MDA level in plasma, and thus provide protection against many chronic diseases by virtue of their free radical scavenging properties [67]. The results on radical scavenging activity of EPAL in this study correspond with that of the oxidative stress markers. Several phytochemicals were reported to act against the deleterious effects of oxidative stress such as triterpenes in aloe vegetables [68], total saponins from \textit{Panax ginseng} [63], polyphenols [55] and flavonoids from \textit{Sideritis raeseri} [69]. This study suggests that \textit{P. americana} leaf is potentially used for averting some diseases associated with oxidative stress.

5. Conclusion

Based on this research, the leaf of \textit{P. americana} has great and promising potential as pharmaceutical agent, particularly to be developed as anti-oxidative agent. This natural approach is thought to be safer and more effective compared to its synthetic agents. Therefore the fruit extract of \textit{P. americana} may play an important role in the development of nutriceuticals and also in the management of oxidative stress induced diabetic mellitus.

**ETHICAL APPROVAL**

All authors hereby declare that; principle of laboratory animals care (NHI publication number 829 revised 1985) were followed, as well as all experiment have been examined and approved by the appropriate ethic committee.
